

LoRA:
Low-Rank Adaptation of Large Language Models

1 Problem statement

Adapting autoregressive language model 1. $P_{\Phi}(y|x)$ to downstream conditional text generation tasks
ex)

- | | | | |
|----|----------------------------------|---------|---------------|
| 1) | | | Summarization |
| 2) | Machine | Reading | Comprehension |
| 3) | Natural Language to SQL (NL2SQL) | | |

and each downstream task is represented by a training dataset of context-target pairs,

2. $Z = \{(x_i, y_i)\}_{i=1, \dots, N}$ where both x_i and y_i sequences of tokens

$$P_{\Phi}(y|x)$$

$$\max_{\Phi} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (P_{\Phi}(y_t|x, y_{<t}))$$

$$P_{\Phi}(y|x)$$

$$P_{\Phi}(y|x) = \prod_{t=1}^T P_{\Phi}(y_t|x_t, y_{<t})$$

$$\max_{\Phi} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (P_{\Phi}(y_t|x, y_{<t}))$$

$$P_{\Phi}(y|x)$$

$$P_{\Phi}(y|x) = \prod_{t=1}^T P_{\Phi}(y_t|x_t, y_{<t})$$

$$\begin{aligned}\mathcal{L}(\Phi) &= -\frac{1}{N} \sum_{i=1}^N \log P_{\Phi}(y_i|x_i) \\ &= -\frac{1}{N} \sum_{i=1}^N \log \left(\prod_{t=1}^T P_{\Phi}(y_{i,t}|x_i, y_{i,<t}) \right) \\ &= -\frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log P_{\Phi}(y_{i,t}|x_i, y_{i,<t})\end{aligned}$$

$$\max_{\Phi} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (P_{\Phi}(y_t|x, y_{<t}))$$

$$P_{\Phi}(y|x)$$

$$P_{\Phi}(y|x) = \prod_{t=1}^T P_{\Phi}(y_t|x_t, y_{<t})$$

$$\begin{aligned}\mathcal{L}(\Phi) &= -\frac{1}{N} \sum_{i=1}^N \log P_{\Phi}(y_i|x_i) \\ &= -\frac{1}{N} \sum_{i=1}^N \log \left(\prod_{t=1}^T P_{\Phi}(y_{i,t}|x_i, y_{i,<t}) \right) \\ &= -\frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log P_{\Phi}(y_{i,t}|x_i, y_{i,<t})\end{aligned}$$

$$\begin{aligned}\Phi^* &= \arg \max_{\Phi} (-\mathcal{L}(\Phi)) \\ &= \arg \max_{\Phi} \left(\frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log P_{\Phi}(y_{i,t}|x_i, y_{i,<t}) \right)\end{aligned}$$

$$\max_{\Phi} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (P_{\Phi}(y_t|x, y_{<t}))$$

The model is initialized to pre-trained weights Φ_0 and updated $\Phi_0 + \Delta\Phi$ by repeatedly following the gradient to maximize the conditional language modeling objective:

$$\max_{\Phi} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (P_{\Phi}(y_t|x, y_{<t}))$$

Problem: For each downstream task, we learn a different set of parameters, **If** the pre-trained **model** is **large**, **storing and deploying** many independent instances of fine-tuned **models** can be **challenging**.

We adopt a more **parameter-efficient approach**:

$$\max_{\Theta} \sum_{(x,y) \in \mathcal{Z}} \sum_{t=1}^{|y|} \log (p_{\Phi_0 + \Delta\Phi(\Theta)}(y_t|x, y_{<t}))$$

2 Aren't existing solutions good enough?

① **Adapter Layers Introduce Latency:**
Large Neural networks rely on hardware parallelism to keep the latency low, and adapter layers have to be processed sequentially.

	Batch Size	32	16	1
	Sequence Length	512	256	128
	$ \Theta $	0.5M	11M	11M
	Fine-Tune/LoRA	1449.4 \pm 0.8	338.0 \pm 0.6	19.8 \pm 2.7
	Adapter ^L	1482.0 \pm 1.0 (+2.2%)	354.8 \pm 0.5 (+5.0%)	23.9 \pm 2.1 (+20.7%)
	Adapter ^H	1492.2 \pm 1.0 (+3.0%)	366.3 \pm 0.5 (+8.4%)	25.8 \pm 2.2 (+30.3%)

Table 1: Inference latency of a single forward pass in GPT-2 medium measured in milliseconds, averaged over 100 trials. We use an NVIDIA Quadro RTX8000. “ $|\Theta|$ ” denotes the number of trainable parameters in adapter layers. Adapter^L and Adapter^H are two variants of adapter tuning, which we describe in Section 5.1. The inference latency introduced by adapter layers can be significant in an online, short-sequence-length scenario. See the full study in Appendix B.

This problem gets worse when we need to shard the model, because the additional depth requires more synchronous GPU operations.

② **Directly Optimizing the Prompt is Hard**

3 Method

3.1 Low-Rank-Parameterized Update Matrices

- hypothesis: the weight updates have a low “intrinsic rank”
- W_0 : pre-trained, frozen
- $\Delta W = BA$: trainable
 - init. A = random Gaussian, $B=0$
 - scale. ΔWx by α/r
 - r is rank, α is constant in r

$$h = W_0x + \Delta Wx = W_0x + BAx$$

Figure 1: Our reparametrization. We only train A and B .

- Generalization of Full Fine-tuning
 - full fine-tuning by setting rank r
 - cf. MLP and prefix-based are cannot take long input seq.
- No Additional Inference Latency
 - $W = W_0 + BA$
 - Able to recover W_0 by subtracting BA

3.2 Applying LoRA to Transformer

- Transformer architecture
 - Four weight matrices in the self-attention module (W_q , W_k , W_v , W_o)
 - two in the MLP module
- Adapting the attention weights only (in this study)
 - freezing the MLP modules
 - for simplicity and efficacy

- Practical Benefits

- reduction in memory and storage usage
- switching between tasks
 - deploying only swapping the LoRA weights (customized models)
- result (on GPT-3 175B)
 - VRAM usage: $\frac{1}{3}$ (1.2TB to 350GB)
 - checkpoint size: 10,000x
 - 25% speedup during training

- Limitations

- not straightforward to batch inputs to different tasks
- not to merge weights if latency is not critical

4 Understanding the low-rank updates

We focus our study on *GPT-3 175B*, where we achieved the largest reduction of trainable parameters (up to 10,000×) *without adversely affecting task performances*.

- 1) Given a parameter budget constraint, which subset of weight matrices in a pre-trained Transformer should we adapt to maximize downstream performance?
- 2) Is the “optimal” adaptation matrix ΔW really rank deficient? If so, what is a good rank to use in practice?
- 3) What is the connection between ΔW and W ? Does ΔW highly correlate with W ? How large is ΔW comparing to W ?

1) Given a parameter budget constraint, which subset of weight matrices in a pre-trained Transformer should we adapt to maximize downstream performance?

	# of Trainable Parameters = 18M						
Weight Type Rank r	W_q 8	W_k 8	W_v 8	W_o 8	W_q, W_k 4	W_q, W_v 4	W_q, W_k, W_v, W_o 2
WikiSQL ($\pm 0.5\%$)	70.4	70.0	73.0	73.2	71.4	73.7	73.7
MultiNLI ($\pm 0.1\%$)	91.0	90.8	91.0	91.3	91.3	91.3	91.7

Table 5: Validation accuracy on WikiSQL and MultiNLI after applying LoRA to different types of attention weights in GPT-3, given the same number of trainable parameters. Adapting both W_q and W_v gives the best performance overall. We find the standard deviation across random seeds to be consistent for a given dataset, which we report in the first column.

2) Is the “optimal” adaptation matrix ΔW really rank deficient? If so, what is a good rank to use in practice?

	Weight Type	$r = 1$	$r = 2$	$r = 4$	$r = 8$	$r = 64$
WikiSQL($\pm 0.5\%$)	W_q	68.8	69.6	70.5	70.4	70.0
	W_q, W_v	73.4	73.3	73.7	73.8	73.5
	W_q, W_k, W_v, W_o	74.1	73.7	74.0	74.0	73.9
MultiNLI ($\pm 0.1\%$)	W_q	90.7	90.9	91.1	90.7	90.7
	W_q, W_v	91.3	91.4	91.3	91.6	91.4
	W_q, W_k, W_v, W_o	91.2	91.7	91.7	91.5	91.4

Table 6: Validation accuracy on WikiSQL and MultiNLI with different rank r . To our surprise, a rank as small as one suffices for adapting both W_q and W_v on these datasets while training W_q alone needs a larger r . We conduct a similar experiment on GPT-2 in Section H.2.

2) Is the “optimal” adaptation matrix ΔW really rank deficient? If so, what is a good rank to use in practice?

$$\phi(A_{r=8}, A_{r=64}, i, j) = \frac{\|U_{A_{r=8}}^{i\top} U_{A_{r=64}}^j\|_F^2}{\min(i, j)} \in [0, 1]$$

Figure 3: Subspace similarity between column vectors of $A_{r=8}$ and $A_{r=64}$ for both ΔW_q and ΔW_v . The third and the fourth figures zoom in on the lower-left triangle in the first two figures. The top directions in $r = 8$ are included in $r = 64$, and vice versa.

Figure 4: **Left and Middle:** Normalized subspace similarity between the column vectors of $A_{r=64}$ from two random seeds, for both ΔW_q and ΔW_v in the 48-th layer. **Right:** the same heat-map between the column vectors of two random Gaussian matrices. See Section H.1 for other layers.

3) What is the connection between ΔW and W ? Does ΔW highly correlate with W ? How large is ΔW comparing to W ?

	$r = 4$			$r = 64$		
	ΔW_q	W_q	Random	ΔW_q	W_q	Random
$\ U^\top W_q V^\top\ _F =$	0.32	21.67	0.02	1.90	37.71	0.33
$\ W_q\ _F = 61.95$	$\ \Delta W_q\ _F = 6.91$			$\ \Delta W_q\ _F = 3.57$		

Table 7: The Frobenius norm of $U^\top W_q V^\top$ where U and V are the left/right top r singular vector directions of either (1) ΔW_q , (2) W_q , or (3) a random matrix. The weight matrices are taken from the 48th layer of GPT-3.

Q&A

Thank you
